Workday VSM

Analyzing Lean Metrics:

- **Total Cycle Time:** ~8 Hours
- **Value Added Ratio:** Low (~25%)
- **Primary Waste Identified:** "Defects/Rework" (Fixing co-worker mistakes) and "Context Switching" (Fragmented project work).

Optimizing the Process:

1. **Eliminating Rework (Defects):** The most critical waste in this value stream is the 1-2 hours spent daily correcting co-worker errors. In Lean terms, this is "Rework."
 - *Optimization:* Implement strict configuration templates or automated scripts that co-workers must use. This forces standardization and prevents the errors from reaching my queue.
2. **Workflow Orchestration (Context Switching):** Project work is currently done "in-between fires," resulting in high context-switching costs.
 - *Optimization:* Implement "Time Blocking." Reserve 1:00 PM - 3:00 PM specifically for project work with a "Do Not Disturb" status, consolidating value-added tasks into a continuous flow.

3. **The "Job Search" Process:** The evening job search represents a total system replacement.

- *Optimization:* Moving the worker (Me) to a new Value Stream with established SOPs and competent peers is the ultimate efficiency gain, eliminating the "Defect" waste entirely.
